Motivation of Fixed Point

Contraction Mapping

Contraction Mapping

Let (X, d) be a metric space. A function $f : X \rightarrow X$ is called a *contraction mapping* if there exists a constant $0 < k < 1$ such that for all $x, y \in X$,

$$d(f(x), f(y)) \leq k \cdot d(x, y).$$

② Example of Contraction Mapping

Consider the function $f : \mathbb{R} \rightarrow \mathbb{R}$ defined by $f(x) = \frac{1}{2}x$. Show that f is a contraction mapping on $\mathbb{R}$ with the standard metric.

② Another Example of Contraction Mapping

Let $X = [0, 1]$ and define $f : X \rightarrow X$ by $f(x) = \frac{1}{2}x + \frac{1}{4}$. Show that f is a contraction mapping on X .

Banach Fixed Point Theorem

💡 Banach fixed point theorem

Let (X, d) be a complete metric space and let $f : X \rightarrow X$ be a contraction with constant $k \in [0, 1)$. Then:

- (i) f has a unique fixed point $x^* \in X$;
- (ii) for every initial point $x_0 \in X$, the iteration

$$x_{n+1} = f(x_n)$$

converges to x^* .

💡 Derivative criterion for contraction on an interval

Let $f : [a, b] \rightarrow \mathbb{R}$ be a differentiable function. If there exists a constant $0 < k < 1$ such that $|f'(x)| \leq k$ for all $x \in [a, b]$, then f is a contraction mapping on $[a, b]$ with the standard metric.

Fixed point iteration method for solving equations

❓ Problem

Solve the equation $x - \cos(x) = 0$ using the fixed point iteration method. Start with an initial guess $x_0 = 1$ and compute the first few iterations to approximate the solution.

Problem

Solve the equation $x^3 - x - 1 = 0$ using the fixed point iteration method. Start with an initial guess $x_0 = 1$ and compute the first few iterations to approximate the solution.

Solving ODEs using Banach fixed point theorem

💡 Equivalent integral form of ODEs

Let $f : [a, b] \times \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function. A function $y : [a, b] \rightarrow \mathbb{R}$ is a solution to the initial value problem

$$y' = f(x, y), \quad y(a) = y_0$$

if and only if it satisfies the integral equation

$$y(x) = y_0 + \int_a^x f(t, y(t)) dt.$$

Picard-Lindelof theorem and the ODE uniqueness theorem

Lipschitz condition

Let $f : [a, b] \times \mathbb{R} \rightarrow \mathbb{R}$ be a function. We say that f satisfies a *Lipschitz condition* with respect to the second variable if there exists a constant $L > 0$ such that for all $x \in [a, b]$ and all $u, v \in \mathbb{R}$,

$$|f(x, u) - f(x, v)| \leq L|u - v|.$$

💡 Picard–Lindelöf / local existence and uniqueness

Suppose f is continuous on a rectangle

$$R = [t_0 - a, t_0 + a] \times [y_0 - b, y_0 + b]$$

and Lipschitz in y there with constant L i.e.

$$|f(t, u) - f(t, v)| \leq L|u - v| \quad \text{for all } (t, u), (t, v) \in R.$$

Let

$$M = \sup_{(t,y) \in R} |f(t, y)|, \quad h = \min \left\{ a, \frac{b}{M}, \frac{1}{L} \right\}$$

(with the convention $1/L = \infty$ if $L = 0$). Then the IVP

$$y' = f(t, y), \quad y(t_0) = y_0$$

has a unique solution on $I = [t_0 - h, t_0 + h]$.

Picard iteration

Picard iteration for solving ODEs

Let $f : [a, b] \times \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function. The Picard iteration is defined as follows:

$$y_0(x) = y_0, \quad y_{n+1}(x) = y_0 + \int_a^x f(t, y_n(t)) dt.$$

Thank You!

We'd love your questions and feedback.
